

Megan O'Halloran

CAP Database

January 27, 2016

1. Screenshots:

Select \*

Customers;

The screenshot shows a PostgreSQL SQL Editor window. The menu bar includes File, Edit, Query, Favourites, Macros, View, and Help. The toolbar contains various icons for file operations, execution, and help. The SQL Editor tab is active, showing a series of SQL commands. Below the editor is a 'Data Output' pane with tabs for Data Output, Explain, Messages, and History. The Data Output pane displays a table with 5 columns: cid, name, city, and discount. The table contains 6 rows of data.

```
VALUES(1023, 'mar', 'c001', 'a04', 'p05', 500, 450.00);

INSERT INTO Orders( ordnum, mon, cid, aid, pid, qty, totalUSD )
VALUES(1024, 'mar', 'c006', 'a06', 'p01', 800, 400.00);

INSERT INTO Orders( ordnum, mon, cid, aid, pid, qty, totalUSD )
VALUES(1025, 'apr', 'c001', 'a05', 'p07', 800, 720.00);

INSERT INTO Orders( ordnum, mon, cid, aid, pid, qty, totalUSD )
VALUES(1026, 'may', 'c002', 'a05', 'p03', 800, 740.00);

2. The primary key is a column that has a unique identifier for its records. A database must always have one primary key. A candidate key can be any column, or combination of columns, that can be a unique key in a database. There can be more than one candidate keys. A candidate key can also be a primary key. The superkey is a set of columns in a table for which there are no two rows that will share the same combination of values. So, the superkey is unique for each and every row in the table. A superkey can also be just a single column.
3. A table could be created for a small business which contains their employees and their information. The name of the table would be MO Employees. The fields of this database would be the following: first name, last name, employee ID, date of birth, social security number, phone number, address, date they were employed, department, and title. The fields date of birth and date they were employed would be the data type datetime, and they are both not nullable. The social security number, phone number and address fields are all char data type and are all not nullable except for the social security number field because an employee could be on a work visa or something else, making it nullable. Finally, the fields labeled first name, last name, department, and title all have the data type varchar and are all not nullable.
4.
  - a. The “first normal form” rule: You must define the data. The data must be looked at, organized into columns and defining their data type, and putting it into the related column. An example of this would be if a business had information about their employees, and creating a table to input all of that information. This rule is important because it states that data must be named and organized, making it easier to access information.
  - b. The “access rows by content only” rule: This states that the only way we can retrieve the information we want is by the content in the row. Some people do not obey this rule and will look things up by the row number ID. However this rule is important because, depending on what you are looking for, things could be out of order. An outsider doesn’t know how the database is organized, it could be organized by order number, or employee ID, so when they look up the information they are looking for, they could get the wrong thing, or numerous things. An example of this rule would be by getting information on a certain product; they would have to find the product number or name.
  - c. The “all rows must be unique” rule: This rule is exactly what it sounds like. The rows in a database cannot be exactly the same. This rule is important because it prevents the problem of having repeated information on the same thing. An

example of this rule would be the employee ID number in a business, which could also be the primary key. This gives every row a unique column, making each row unique.
